Web 4.0 beyond... or digital revolution in health care economics?

Some concepts of industrial Web 4.0 can be applied to medicine

Industry seeks to create a flowing process with Web 4.0

With a Medical 4.0 strategy new concepts such as telemedicine and the digitalisation of work processes for doctors, nurses and hospital administration can take a central role

According to a study by consultants Roland Berger, 90% of all hospitals in Germany have developed a digitalisation strategy.

The areas of action for the transformation within the hospital are extensive. Such areas include among others:

- Electronic patient records,
- Telemedicine,
- IT security and assistance and
- Nurse robots

However, in order to successfully implement digital change, there must be more acceptance of new concepts such as telemedicine and nurse robots among patients.

The advantages

- Digitalisation can make the healthcare system much more effective
- Automatic medication distribution in hospitals reduces errors and gives nurses more time to spend with patients
- Changing to paperless work can cut administrative work for doctors and nurses, bring an increase in medical care quality and better economic performance

Fritz Kahn (*1888) - grandfather of modern data visualization.

Millions of patients to see doctor by Skype

Times

8.1.2019 Doctor WHO?

The question is not if the patients can see their doctor via video consultation, but if the doctors are ready to see/treat patient via video.

NO systematic or structured training yet at most medschools or during postgraduate training in medical video consultancy (MVC)

Millions of patients to see doctor by Skype

Times

8.1.2019 Doctor WHO?

Still “good old times” bed side teaching.

It is completely different to look, feel and sometimes smell – compared to a 2D video window.

- The Emergency Department Express Care program at New York-Presbyterian/Weill Cornell Medicine has established one of the first telemedicine programs in its academic hospital emergency department.
- The goal is to reduce the amount of time a patient with a non-urgent medical condition has to wait for care.
- The hope is to provide more efficient care for these patients without compromising the quality of care received.
- The initial results are promising since wait time has dropped from an average of 2 to 2.5 hours to only 35 to 40 minutes.

ABSTRACT

Objective The purpose of this study was to assess whether a photoplethysmography (PPG) sensor in a smart watch can accurately recognise the return of spontaneous circulation (ROSC) in cardiac arrest patients compared with carotid artery palpation.

Methods This prospective observational study was conducted on 50 out-of-hospital cardiac arrest patients who visited the emergency department (ED) of one tertiary hospital. As soon as the patient arrived at the ED, advanced cardiac life support was carried out immediately. At this time, three smart watches were attached to the carotid artery, forehead and wrist and were checked for pulse measurements every 2 min. In the case of ROSC, blood pressure, heart rate and heart rate regularity were confirmed, and pulse was simultaneously measured at three sites with smart watches. In the case of no ROSC, only the pulse was measured at three sites with the smart watches.

Results There were 33 males (66%) and the mean age was 68 ± 11.57 years. In 14 patients (28%), spontaneous circulation was recovered through cardiopulmonary resuscitation, and all survived. The sensitivity and specificity of manual palpation were 78.6% and 90.4%, respectively. False-positive and false-negative rates were 9.6% and 21.4%, respectively. Smart watches at all three sites had the same or higher sensitivity than manual palpation. The sensitivity of the smart watch was the highest, at 100%, in the carotid region and the lowest, at 78.6%, in the wrist region. The specificity of the smart watch was the highest, at 100%, in the wrist region and the lowest, at 78.7%, in the carotid region.

Conclusion Compared with manual pulse check, the PPG sensor embedded in the smart watch showed the same sensitivity and a higher specificity for recognising ROSC when measured at the wrist.

INTRODUCTION

Carotid artery palpation of a cardiac arrest patient is key to allowing the rescuer to

Strengths and limitations of this study

- We studied the feasibility of using smart watches for the recognition of cardiac arrest or return of spontaneous circulation during cardiopulmonary resuscitation.
- In this study, we attempted to investigate whether the limits of manual pulse checking can be overcome by using smart watches.
- Each investigator was blinded to the values measured to increase confidence in the results.
- One limitation of this study is the use of just one smart watch (Galaxy R).
- Another limitation is that we did not investigate other environments and situations in a prehospital setting.

recognise the return of spontaneous circulation (ROSC) and determine the next action.¹ However, 'carotid artery palpation' is recommended only by the healthcare provider and does not exclude the possibility of error even if performed by an expert.^{2,3} The recognition of ROSC using capnography, arterial blood pressure monitoring and ultrasound is highly reliable, but these techniques are not always available, especially in out-of-hospital settings.⁴ Therefore, a more accurate and simple way to recognise ROSC than 'carotid artery palpation' would help less experienced rescuers make accurate decisions. In a recent animal study, photoplethysmography (PPG) was reported to be available in cardiac arrest situations.⁵ Most current smart watches have PPG sensors for pulse measurement. PPG, the technology found in standard pulse oximeters, measures light reflectance in tissue to detect arterial pulsations. Therefore, the aim
